

7.6 Troubleshooting: Diagnosing Retrieval Friction

Use this decision tree when a Pull-and-Deploy test exceeds sixty seconds. The friction is always local. The fix is always small.

Step 1 – Where did the navigation slow down?

Symptom	Diagnosis	Fix
I hesitated at a folder level, unsure which folder to click	The folder label is too vague	Rename it with a more specific descriptor
I opened the correct folder but hesitated between two or more files	The file names are too similar	Add a distinguishing tag to each name
I had to click through more than four levels to reach the file	The nesting is too deep	Flatten one level by combining two subfolders
I opened the wrong file and had to go back	The file name does not match the content	Rename the file to reflect what it actually contains

Step 2 – Apply the single fix. Re-test. Confirm the retrieval lands under sixty seconds.

If the friction persists after one fix, check whether you applied a scene-type template without confirming it matches your genre calibration. The two layers stack. The genre calibration sets the range. The scene-type template modulates within it. Verify both are present and correctly ordered in your file, then re-test.
